Manuscript received on 12 May 2017.

O n a recent birdwatching trip to Arunachal Pradesh we observed and photographed one unidentified starling (Aves: Sturnidae) at Dirang in West Kameng District (27.35°N, 92.24°E Alt: 1600m), on 17 April 2017 at 1600 hrs. The bird was later identified from the photographs as a White-cheeked Starling *Spodiopsar cineraceus*, a species that had never been recorded in India earlier [103].

The lone bird was seen, in flight, following a flock of Spotted Doves *Streptopelia chinensis* on a farmland (mixed cultivation of rice and corn) bordered with groves of bamboo. The starling and the doves alighted in a field of corn, which had recently been harvested. We saw it foraging by walking on the ground and probing the soil with its bill to capture insect prey. Its back was dark brown; it had a black crown, and a greyish belly contrasting with a darkish breast [104, 105]. There was a conspicuous white patch extending from the sides of the crown to the cheek, under the eye and up to the base of the lower mandible. Its beak was bright orange, with a dark base on the lower mandible, and its legs were bright orange as well. Though the sexes of the White-cheeked Starling are distinguishable in the field, individual variations in plumage characteristics are reportedly high, often precluding a positive identification of gender unless a pair is seen together (Yamaguchi 2011). We re-visited the site on 18 April 2017 from 1500 hrs to 1730 hrs, but could not locate the bird.

The White-cheeked Starling breeds in eastern Asia from south-eastern Transbaikal to the Ussut River, southwards through central and eastern Mongolia, Manchuria, northern China west to eastern Qinghai and the Sichuan Provinces, and eastwards to Korea, the southern parts of Sakhalin, southern Kurile Islands, and Japan. The species is notably migratory, wintering in southern China, Hong Kong, and Taiwan and has been known to straggle into Myanmar, Thailand and the Philippines (Feare & Craig 1999). In China it is common throughout its breeding range (Cheng 1987), and is seen in flocks of thousands in its regular range. This is also a bird of flat lowlands, although locally common up to 1200 m.
There are no previous records of the White-cheeked Starling from the Indian Subcontinent (Ali & Ripley 1987; Grimmett et al. 2011), and Rasmussen & Anderton (2012) treat it as possible in the extreme north-eastern part of the region. As such, this species is not included in the India Checklist (Praveen et al. 2016). Our report, therefore, makes it the first confirmed record of the species from India.

Given its propensity towards vagrancy in winter, evident from the isolated reports from South-east Asia, we believe that the bird we saw was probably also a vagrant.

Acknowledgements
We thank Adesh Shivkar, and Pritam Baruah for reconfirming the identity of the species from the photographs. We also thank Praveen J. and Pritam Baruah for their guidance and suggestions for this manuscript.

Manuscript received on 26 April 2017.

The Mishmi or Rusty-throated Wren-babbler Spelaeornis badeigularis was long known only from a single specimen (USNM #390355) collected on 05 January 1947 at about 1900 m at Dreyi (Ripley 1950), SE Lohit Frontier Division (28°05’N, 96°20’E; Lozupone et al. 2004; Fig. 1). After many years, during which the Mishmi Hills were inaccessible to ornithologists, permit regulations were relaxed and the species was rediscovered on 18 November 2004 by King & Donahue (2006) near the ‘km 44’ sign along the Roing–Hunli road, Rt. 313. King & Donahue (2006) eventually encountered a total of 17 individuals at various locations between 1700–2400 m asl as far north as between Mayodia Pass and Hunli, but noted that they seemed much less common on the northern side of Mayodia Pass.

Editorial comment: The White-cheeked Starling Spodiopsar cineraceus is accepted into the India Checklist, based upon this note.
